

POOL COPING AND WATER LINE TILING – FIBREGLASS AND CON-CRETE SWIMMING POOLS

INTRODUCTION & SCOPE

A typical construction method for swimming pools is to install a preformed fibreglass liner into the ground, usually with a concrete surface or Compressed Fibre-Cement (CFC) sheet surround deck. This liner has a visible horizontal top edge around 100-150mm wide where the coping tiles are to be laid. It is a common request made to DUNLOP to supply an adhesive that will bond a coping tile to the top edge of the pool, and often the inquirer wants to span the joint between the liner and the surround.

In this bulletin we will examine why such a course of action is not a sound practice, and some suggested ways to install tiles or 'pavers' in this situation. We will also briefly look at bonding waterline tiles within the pool as well.

Note: If the pool liner is concrete rather than fibreglass, the same rules about joints in this discussion still apply.

THE REQUESTED DETAIL

The usual request made is, 'what adhesive would you recommend for the installation of coping tiles on a fibreglass pool edge?' A bit of further inquiry to the customer reveals that it is intended to bond the tiles across the boundary between the liner and onto the surround. Usually these tiles are large format and both overhang the water and extend on the surrounds. In other words, the tile covers over the joint to create an homogenous tile appearance to the finished job.

WHAT IS THE PROBLEM?

What is the problem with this scenario? Well, the problem with having

a solidly fixed tile across the pool surround boundary in this way, is that it spans what is in effect a movement joint. The definition of a movement joint in this particular case can be found in the tiling standard AS3958.1-2007,

'Clause 5.4.5.3 Movement joints should be installed at the following locations:

c) At junctions between different background materials, when cladding is continuous across varying types of background'

and

'E2.10 Movement joints

...Movement joints should be inserted to coincide with the structural junction of the pool shell and the surrounding slab..'

What are the consequences of ignoring this requirement and tiling straight across the boundary? The pool shell and surround are made from two different materials with different expansion and movement characteristics creating unbalanced movements either side of the joint. Also the pool fill and substrate below the surround create differences in movement due to their thermal properties, expansion and contraction during water absorption of the soil, structural movement of decks and in the case of the pool water itself, movements and seiching due to winds or pressure loading due weight falling into the pool (i.e. diving). These factors mean that anything rigidly bonded across the joint will very likely crack as shown in Fig.1 on the next page.

A second option occasionally suggested is to only adhere the tile one side of the joint or the other. Usually this is the concrete side since the width of the fibreglass edge is usually less than 150mm and therefore the concrete provides a larger and ultimately more compatible surface to bond to. However, this leaves the edge of the tile cantilevered and subject to breakage due to lever arm moments from swimmers climbing out of the pools, or flexural compressive forces from being stood on. This situation is shown in Fig.2 on the next page.

DESIGN SOLUTIONS

The preferred solution as specified in the standard is to create a movement joint around the edge of the pool that corresponds to the shell-surround boundary. The general design is shown in Fig.3. The major point with this detail is that it might require the tiles or pavers be cut to create the joint which adds an extra process, but also affects the aesthetics of the finished job.

Another solution is to bond the tile to the surround side with a modified cement based tile adhesive, and to the pool rim with either a flexible sealant or sealant adhesive. For example, the pool side bond could be performed with a well spread polyurethane, epoxide, silaneurethane, or even suitable silicone sealants (>75% coverage is required rather than a few thin beads). This design is more difficult to do because it uses two separate products on the same tile, but effectively eliminates the flexing of an unsupported tile, and allows the system to move because of the low E-modulus of the sealant. Caution may be required with CFC decks as they may move more than concrete (the framing) and possibly even exceed the capabilities of the sealant. This design is shown in Fig.4 on page 3, for a concrete surround.

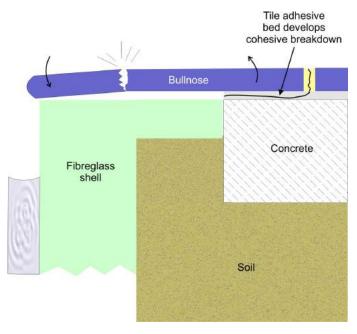

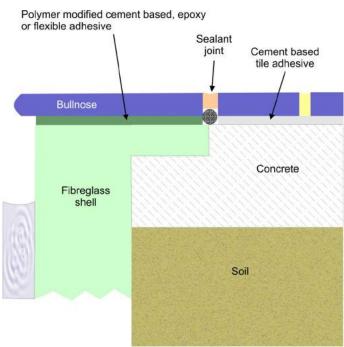

Figure 2. Effect of cantilevered unsupported tiles subjected to either bending moments from swimmers exiting the pool, or compressive flexure from being stood on.

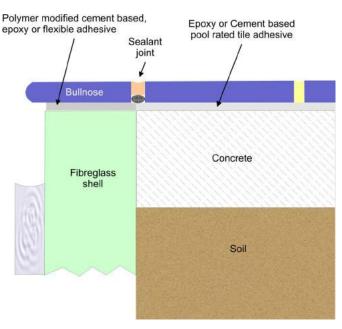

Figure 3. Examples of details showing the presence of the movement joint, and the cut that may be required in the bull-nose tile. The position is ultimately dependent on the shape of the shells lip.

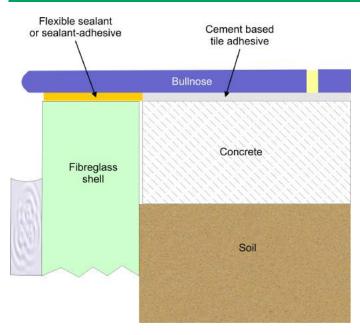

Figure 4. An installation using the sealant/adhesive and normal tile adhesive combination rather than cutting the tile for a visible joint.

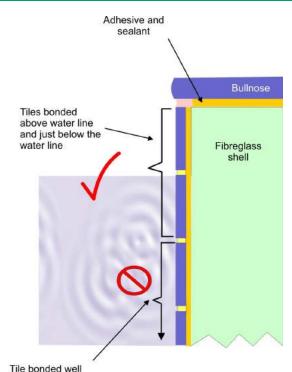

Figure 5. The bonding of tiles to the upper edge of the fibreglass pool liner and to just below the waterline is acceptable, but not at depth below the waterline.

WATERLINE TILES

The final part of this installation is usually the placement of water line tiles. DUNLOP has a recommendation for bonding tiles above, on, and just below the waterline for fibreglass pools, but not at depth. There are no such restrictions on concrete pools where the correct adhesive is used. Figure 5 shows the general arrangement.

In this situation it is critical to make sure that the correct adhesive is used and that the pool shell is properly prepared. Bonding tiles to the fibreglass for waterline tiles – the fibreglass gelcoat surface needs to be roughened which may compromise the integrity of the liner if done excessively. Roughened means, that the surface of the fibreglass gel coat shall be mechanically prepared such 100% of the surface is treated to produce a rough surface finish of equivalent appearance to CSP2 or CSP3 (see Fig.7 overleaf). The fibreglass fibrils must be visible however, this process of preparation also has the potential effect of exposing n the fibreglass to adhesive attack.

below the waterline to pool base

A final note concerning pool tiles, where sheet mosaic tiles are used, they must be of a type that is not

Figure 6. An example of a tiling installation where the pool shell has not been properly prepared prior to the application of 'waterline tiles'. The adhesive has not bonded.

affected by water immersion. The

TOLL FREE SERVICE 1800 222 841 (Aust), 0800 224 070 (NZ)

tiles must not be fixed to any 'backing' material such as mesh with an adhesive that is water softening or soluble. Also, the tiles need to have at least 85% of the back face of the tile available for the adhesive contact. Where these conditions are not observed, failures of the tiling are a significant risk (see Fig.8).

A CASE HISTORY OF POOR INSTALLA-TION PRACTICES

The pictures Figs. 9 to 11 show a fibreglass pool installation where the general rules given above were not followed (including defects shown in Fig 8). In this particular situation the paving coping tiles were bonded directly across the ring beam joint between the pool shell and the surrounding concrete, a non-approved type of rubber modified adhesive was used, and poor adhesive application and tile bedding were evident.

The pool was installed circa 2007, and the problems were evident at some time between 2012 and 2015. The pavers were loose and unsafe at the time these pictures were taken.

RECOMMENDED ADHESIVE SYSTEMS

The following DUNLOP tiling and accessory products are recommended for this type of installation.

Masonry

- Bonding tiles to the concrete or DUNLOP UNIVERSAL ADHESIVE. compressed fibre-cement pool surrounds or inside concrete pools shells (not fibreglass shells) -

DUNLOP TILE ALL

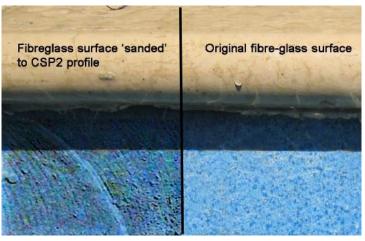

Figure 7. A schematic showing a fibre-glass pool that has been surface prepared to CSP2 profile.

Figure 8. An example of mesh mosaic tiles that have failed at the waterline because of an inappropriate adhesive choice for a fibre-glass pool shell, but also because the mesh adhesive was water softening and obstructed the adhesive contact coverage with the tile itself.

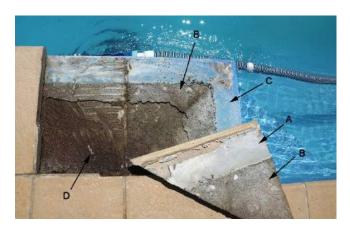

Fibreglass

- Bonding to fibreglass pool at and above the waterline with shells that main adhesive bed is applied with an are correctly prepared.

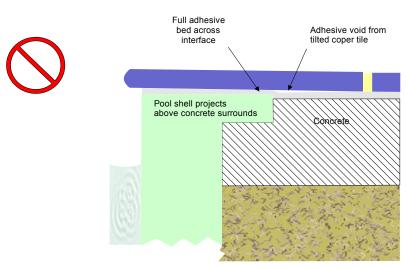

DUNLOP TILE ALL - after preparation an initial skim coat 1mm thick is applied with a flat bladed trowel, and allowed to cure for 4 hrs, then the appropriate notch trowel for the tile

size as defined in AS3958, prior to application of the tiles).

The best performance on this type of pool shell is really obtained with an epoxy adhesive. For this type of adhesive recommendation refer to DUNLOP for more information on an appropriate ARDEX epoxy.

Sealants/Grouts

Sealant/adhesive suitable for bonding to the fibreglass top edge under the coping tiles, and not underwa-

DUNLOP TILE ALL PLUS

For a neutral cure silicone alternative consult DUNLOP for an Ardex alternative material.

Grouts are

Epoxy grout -
